Identity, Security and XML Web Services

Jorgen Thelin
Chief Scientist
Cape Clear Software Inc.

E-mail: Jorgen.Thelin@CapeClear.com
Abstract

The use of security credentials and concepts of single-sign-on and “identity” play a big part in Web Services as developers start writing enterprise-grade line-of-business applications. An overview is provided of the emerging XML security credential standards such as SAML, along with various “identity” standards such as Passport and Liberty. We examine how “identity aware” Web Service implementations need to be, and the value a Web Services platform can add in reducing complexity in this area, with lessons drawn from experiences using J2EE technology for real-world security scenarios.
Agenda

- The Concept of Identity
- Web Services and Identity
- Interoperable XML Security and Identity
- Examples of Security Credentials in SOAP
- Single-sign-on
- Identity Awareness in Web Services
Cape Clear Software Inc.

- Start-up founded in 1999 by several executives from Iona Technologies
- Venture capital funding from Greylock and Accel Partners
- Offices in:
  - Dublin, Ireland
  - London, UK
  - San Mateo, CA, USA
  - Waltham, MA, USA

- The company is totally focused on XML Infrastructure, including Web Services
- Products:
  - Web Services Development tool set
  - XML Integration Server supporting Web Services
  - **FREE** WSDL Editor

http://www.CapeClear.com

A Definition of Identity

Definition from Cambridge Dictionaries Online:

- **Identity**
  - [ noun ]
  - Who a person is, or the qualities of a person or group which make them different from others

- [http://dictionary.cambridge.org/define.asp?key=identity*1+0](http://dictionary.cambridge.org/define.asp?key=identity*1+0)
What is Identity?

At its most basic, the concept of Identity is about:

- Who you are
- How you prove who you are
- What that allows you to do
Identity – Who are you?

- An identity equates to a particular **subject** or principal
  - For example: Joe Bloggs ...
  - ... Who lives at 123 My Street, Your Town

- Usually equates to a **person**, but could also be a **group**, **corporation**, or even something like an automated **software agent component**

- Subjects must be distinguishable
  - May be another Joe Bloggs living at 125 My Street
Identity – Proof of identity

How do you prove who you are?

In real life, this is usually thru some official documents such as:

- Driving License
- Passport

In computing terms, a user has a set of security credentials such as:

- username + password
- X509 certificates
Identity – Permissions

- What does this identity prove about us?
- What does this identity allow us to do?

Some real life examples:

- Holding a UK passport proves I am a UK Citizen
- Being a UK Citizen allows me to work in the UK
- Losing my passport does not stop me being a UK Citizen; it just makes it harder to prove that I am.

- A standard driving license shows I am allowed to drive a car
- I am not allowed to drive a Heavy Goods Vehicle unless I hold a HGV Driving License
Identity – Permissions and Credentials

- The **permissions** and entitlements for an identity is ultimately determined by the set of credentials that were presented to assert that identity.

- Permissions and credentials are use to make policy enforcement decisions
  
  - Am I allowed to drive a Heavy Goods Vehicle?
  - Am I allowed to work in the UK?
  - Am I allowed to work in the US?
Web Services and Identity

- How does this affect Web Services?

- Security and Identity is a **fundamental** requirement of any **real-world** deployment of a Web Services application

- Ultimately all **security policy decisions** are based on the caller’s identity

- The challenge is to how to represent and prove a caller’s identity in an open and **interoperable** way.
Web Services and Identity 2

Security and identity considerations for a Web Services application:

- **Authentication**
  - Who is the caller?
  - How did they prove their identity?
  - Do we trust the source of these credentials?

- **Authorization**
  - What is the caller allowed to do?

- **Attributes**
  - What other facts do we know about the caller?
    - For example, e-mail address, department, employee number
  - How do we use this attribute information in the application?
    - For example, customizing the data returned based on display preferences
End-to-end Security Credentials

[Diagram showing a network with labeled components: Client, WS Gateway, Public Internet, WS Gateway, WS Broker, CORBA, EJB, Web Service, Firewall]

XML security credentials

“The Last Mile”
Interoperable Security Credentials

- To achieve interoperable security and identity, web services require the following

- Standard ways to:

  1. Representing security credential data in XML
     - Eg. SAML – Security Assertions Markup Language specification

  2. Obtaining credential data
     - Eg. Single-sign-on services such as Microsoft Passport or Liberty Alliance specifications

  3. Transport credential data in a SOAP message
     - Eg. SOAP header fields defined in the WS-Security specification
WS-Security

- **Owner:** Microsoft/IBM/Verisign – Now OASIS WSS-TC  
- **Status:** WIP for OASIS standardization process

**Purpose:**
- Provides a model for many levels of security needed for web services.  
- A general-purpose mechanism to associate security-tokens with messages  
- Describes how to encode binary security tokens in messages using SOAP Headers  
- Includes enhancements to SOAP to provide quality of protection mechanisms

**Notes:**
- Builds on top of XML Digital Signatures and XML Encryption specifications  
- WS-Security Addendum adds  
  - Facility for timestamp and TTL headers  
  - Provides greater protection when passing around passwords and security certificates

**More Info:**

- WS-Security AppNotes - provide guidance to implementers of the WS-Security specification:  
The WS-Security specification set defines the following tokens:

- Unsigned security tokens
  - Username

- Signed security tokens
  - X.509 certificates (binary)
  - Kerberos tickets (binary)

- XML security tokens
  - Any XML token, such as SAML
  - Usually self verifying / signed
Typical XML Security Dialogue – Non Self-Validating Credentials

Need to query the security service to validate the credentials
Typical XML Security Dialogue – Self Validating Credentials

1. Authentication request
   - Web Service Client

2. Authentication credentials / token
   - Security Authority
     - Web Service
     - e.g. SAML

3. Web Service Request including security credentials / token
   - Application
     - Web Service

4. Web Service Response

No need to query the security service to validate the credentials.

Usually done by the security authority digitally signing the credentials.
SAML v1.0

- SAML – Security Assertions Markup Language
  - An XML-based framework for exchanging security information
  - A specification published by the OASIS organization

- The SAML specification defines:
  - How to represent security credentials ("Assertions" in SAML parlance) using XML
  - An XML message exchange protocol for querying a SAML Authority service

- SAML does not define:
  - How to obtain security credentials ("Assertions") in the first place
SAML Assertion Types

❖ SAML Authentication Assertions
  • The results of an authentication action performed on a subject by a SAML authority

❖ SAML Attribute Assertions
  • Attribute information about a subject

❖ SAML Authorization Assertions
  • Authorization permissions that apply to a subject with respect to a specified resource
A Username Token in WS-Security SOAP Header

```xml
<SOAP:Envelope xmlns:SOAP="...">
  <SOAP:Header>
      <wsse:UsernameToken>
        <wsse:Username>jthelin</wsse:Username>
        <wsse:Password Type="wsse:PasswordDigest">XYZabc123</wsse:Password>
        <wsse:Nonce>h52sI9pKV0BVRPUolQC7Cg==</wsse:Nonce>
      </wsse:UsernameToken>
    </wsse:Security>
  </SOAP:Header>
  <SOAP:Body Id="MsgBody">
    <!-- SOAP Body data -->
  </SOAP:Body>
</SOAP:Envelope>
```
<wsse:Security
    xmlns:wsse="http://schemas.xmlsoap.org/ws/2002/12/secext">

    <wsse:BinarySecurityToken  Id="X509Token"
        xmlns:wsse="http://schemas.xmlsoap.org/ws/2002/12/secext"
        ValueType="wsse:X509v3"
        EncodingType="wsse:Base64Binary">
        MIIEZzCCA9CgAwIBAgIQEmtJZc0...
    </wsse:BinarySecurityToken>

    <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
        <ds:SignedInfo>
        ...
        </ds:SignedInfo>
        <ds:SignatureValue>
        ...
        </ds:SignatureValue>

        <ds:KeyInfo>
            <wsse:SecurityTokenReference>
                <wsse:Reference URI="#X509Token" />
            </wsse:SecurityTokenReference>
        </ds:KeyInfo>
    </ds:Signature>

    ...
</wsse:Security>
A SAML Assertion in WS-Security SOAP Header

```xml
<wsse:Security
 xmlns:wsse="http://schemas.xmlsoap.org/ws/2002/12/secext">
  <saml:Assertion
   xmlns:saml="urn:oasis:names:tc:SAML:1.0:assertion"
   MajorVersion="1"
   MinorVersion="0"
   AssertionID="SecurityToken-mc375268"
   Issuer="mycompany"
   IssueInstant="2002-07-23T11:32:05.6228146-07:00" > 
    ...
  </saml:Assertion>

  <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
    <ds:SignedInfo> ...
    <ds:SignatureValue> ...
    </ds:SignatureValue>

    <ds:KeyInfo>
      <wsse:SecurityTokenReference>
        <saml:AssertionIDReference>
          SecurityToken-mc375268
        </saml:AssertionIDReference>
      </wsse:SecurityTokenReference>
    </ds:KeyInfo>
  </ds:Signature>

  ...
</wsse:Security>
```
Single-sign-on Services

SSO Services provide:
- a single point of logon and authentication
- a standardized way to obtain suitable credentials to prove the authenticated identity

The main contenders using XML are:
- Liberty Alliance
- Microsoft Passport
- Proprietary security products such as Netegrity SiteMinder are adding direct SAML interfaces
- WS-Trust – new spec for standardized XML interface

Still remains an area needing standardization
Liberty Alliance

- The Liberty Alliance Project is a cross-industry group aiming to establish an open standard for federated network identity

- [http://www.projectliberty.org/](http://www.projectliberty.org/)

- The Liberty specification v1.0 has two main facets:
  - Single sign-on
  - Identity federation
Microsoft .NET Passport

- Microsoft .NET Passport is a suite of Web-based services that makes using the Internet and purchasing online easier and faster for users.

- .NET Passport provides users with
  - Single sign-in (SSI)
  - Fast purchasing capability at participating sites

- Microsoft is upgrading the current Passport facilities to
  - Provide an XML interface
  - Support federation
  - Use Kerberos v5 as the underlying mechanism for securely exchanging credentials
The Need for a Sign-on Standard – WS-Trust

- The need remains for a “sign-on standard” to avoid reliance on proprietary interfaces

- WS-Trust
  - A proposed specification in the WS-Security family
  - Provides a standardized interface for acquiring security tokens
  - Still very early in the standardization process, but the most likely candidate for a common interface

WS-I Basic Security Profile

From the charter for the new WS-I Basic Security Profile work group:

- The BSP-WG will develop an interoperability profile dealing with transport security, SOAP message security, and other Basic Profile-oriented security considerations of Web Services

- Although this will not cover all aspects of the emerging XML Security specifications, it will certainly solidify the base levels.
Identity-awareness in Web Services

Do web services themselves need to be identity-aware?

- Not really, in most cases
- A mature web services platform product such as Cape Clear Server can handle almost all the “boilerplate” work of authentication and enforcement of access control lists
Most standard authentication and authorization functions are best done in a uniform manner by the platform, rather than being implemented on an application-by-application basis.

- Interceptor plugins allow this to be a deployment policy decision rather than an implementation decision.
Web Service application only needs to be Identity-aware if it needs to use attributes asserted for the *caller*

- For example, reading the delivery address from the user’s MS Passport record
Desired Web Services platform security

- The goal will be declarative security functions for web services just like EJB
  - So, having declarative statements of security policy for an Web Service application:
    - Required transport security attributes (for example, “Callers must use encrypted / SSL connections”)
    - Required message security attributes (for example, “Messages must be digitally signed”)
    - Permitted authentication realms / single-sign-on services
    - Role-based access control lists applied at the granularity of the operation / method call.
  - This places control of security to application administrators rather than developers.
Summary

“Identity” is one of the fundamental concepts behind all the security mechanisms in line-of-business Web Services

Having a standard XML-based serialized form of credentials is vital for true end-to-end interoperability

Standardization of specifications for credential exchange and single-sign-on using XML and SOAP are still incomplete, so true interoperability is not yet possible.

WS-I Basic Security Profile is working to guarantee interoperability of transport and message level security for Web Services

Use a mature Web Services runtime platform such as Cape Clear Server to handle most “boilerplate” security tasks such as enforcing authentication and authorization requirements
